## Paired data

Gather 100 rats and determine whether they are infected with viruses $A$ and $B$.

## Underlying probabilities

|  | I-B | NI-B |  |
| :---: | :---: | :---: | :---: |
| I-A | 9 | 9 | 18 |
| $\mathrm{NI}-\mathrm{A}$ | 20 | 62 | 82 |
|  | 29 | 71 | 100 |

|  | B |  |
| :---: | :---: | :---: |
|  | 0 | 1 |
| A 0 | $\mathrm{p}_{00}$ | $\mathrm{p}_{01}$ |
| 1 | $\mathrm{p}_{10}$ | $p_{11}$ |
|  | $\mathrm{p}_{+0}$ | $\mathrm{p}_{+1}$ |

$\longrightarrow$ Is the rate of infection of virus $A$ the same as that of virus $B$ ?
In other words: Is $\mathrm{p}_{1+}=\mathrm{p}_{+1}$ ? Equivalently, is $\mathrm{p}_{10}=\mathrm{p}_{01}$ ?

## McNemar's test

$H_{0}: p_{01}=p_{10}$

Under $H_{0}$, e.g. if $p_{01}=p_{10}$, the expected counts for cells 01 and 10 are both equal to $\left(n_{01}+n_{10}\right) / 2$.

The $\chi^{2}$ test statistic reduces to $X^{2}=\frac{\left(n_{01}-n_{10}\right)^{2}}{n_{01}+n_{10}}$

For large sample sizes, this statistic has null distribution that is approximately a $\chi^{2}(\mathrm{df}=1)$.

For the example: $X^{2}=(20-9)^{2} / 29=4.17 \longrightarrow P=4.1 \%$.

## An exact test

Condition on $\mathrm{n}_{01}+\mathrm{n}_{10}$.

Under $\mathrm{H}_{0}, \mathrm{n}_{01} \mid \mathrm{n}_{01}+\mathrm{n}_{10} \sim \operatorname{Binomial}\left(\mathrm{n}_{01}+\mathrm{n}_{10}, 1 / 2\right)$.

In R, use the function binom. test.
$\longrightarrow$ For the example, $\mathrm{P}=6.1 \%$.

## Paired data

|  | Paired data |  |  | Unpaired data |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | I-B | NI-B |  |  | 1 | NI |  |
| I-A | 9 | 9 | 18 | A | 18 | 82 | 100 |
| NI-A | 20 | 62 | 82 | B | 29 | 71 | 100 |
|  | 29 | 71 | 100 |  | 47 | 153 | 200 |
| $\rightarrow \mathrm{P}=6.1 \%$ |  |  |  | $\rightarrow \mathrm{P}=9.5 \%$ |  |  |  |

$\longrightarrow$ Taking appropriate account of the "pairing" is important!

## Deviations from Random Coil Behaviour

Are there site-specific deviations from random coil dimensions?
Förster Resonance Energy Transfer enables us to measure the distance between two dye molecules within a certain range. This can be used to study site-specific deviations from random coil dimensions in highly denatured peptides.

## Deviations from Random Coil Behaviour

## Deviations from Random Coil Behaviour

We have two underlying distributions for the green and red photons:

- One stemming from a peptide only having a donor dye.
- One stemming from a peptide being properly tagged with a donor and an acceptor dye.

Assume a photon has probability $p_{0}$ of being red in the former situation, and $p_{1}$ in the latter.

## Deviations from Random Coil Behaviour

## Deviations from Random Coil Behaviour

Assume we observe $n_{i}$ photons at time point $i$. Then the number of red photons is simply Bernoulli $\left(n_{i}, p_{i}\right)$, where $p_{i}$ is either $p_{0}$ or $p_{1}$. Assume that the probability of observing photons from a peptide without an acceptor dye at any time is $p$, independent of the total number of photons observed. Let $X$ be the number of red photons. Then

$$
\begin{aligned}
P\left(X=x_{i} \mid n_{i}\right) & =P\left(X=x_{i} \mid n_{i}, p_{0}\right) \times p+P\left(X=x_{i} \mid n_{i}, p_{1}\right) \times(1-p) \\
& =\binom{n_{i}}{x_{i}} p_{0}^{x_{i}}\left(1-p_{0}\right)^{n_{i}-x_{i}} \times p+\binom{n_{i}}{x_{i}} p_{1}^{x_{i}}\left(1-p_{1}\right)^{n_{i}-x_{i}} \times(1-p),
\end{aligned}
$$

and hence

$$
L\left(p, p_{0}, p_{1}\right)=\prod_{i=1}^{N}\left[\binom{n_{i}}{x_{i}} p_{0}^{x_{i}}\left(1-p_{0}\right)^{n_{i}-x_{i}} \times p+\binom{n_{i}}{x_{i}} p_{1}^{x_{i}}\left(1-p_{1}\right)^{n_{i}-x_{i}} \times(1-p)\right] .
$$
